Abstract

This study was designed to investing the drug prescribing pattern which is the important point in the rational or irrational use of drugs among patients dispensing their prescriptions from the private pharmacies in Maysan governorate, Iraq for a period of 1 month. The data collected from prescriptions were calculated and analyzed according to the WHO prescribing guidelines. The data showed that the mean of drugs included in single prescription was 3.4, and 12% of prescribed drugs were written as generic names; moreover, the percentage of antibiotics, corticosteroids and anxiolytics were 33.3%, 11.4% and 23.8% respectively. Those results indicate the irrational use of drugs when compared with the world health organization standard values of prescribing indicators, in addition to the bad prescriptions (analyzed in the present study) written by specialized physicians. In conclusion, actual intervention and follow up, training on rational use of drugs and intervention strategies for prescribers is required to improve the rational use of drugs.

Key words: prescription pattern, polypharmacy, rational drug use

نموذج الوصف والاستعمال الأمثل للدواء في محافظة ميسان / العراق حيدر فخري التكمجي *^١ و عبد الرسول محمود ويس ** *فرع الصيدلة السريرية، كلية الصيدلة ، جامعة بغداد،بغداد ، العراق ** فرع الأدوية والسموم ، كلية الصيدلة ، جامعة بغداد،بغداد ، العراق

الخلاصة

صممت هذه الدراسة لتحديد طريقة وصف العلاج و هو عنصر مهم في تحديد الاستخدام الأمثل أو غير الأمثل للدواء بين المرضى المراجعين للصيدليات الأهلية في محافظة ميسان/العراق ولمدة شهر واحد. جمعت البيانات وحللت اعتماداً على مقاييس منظمة الصحة العالمية وقد اظهرت هذه البيانات بان معدل الادوية الموصوفة في كل وصفة، النسبة المئوية لعدد الأدوية الموصوفة باستخدام الاسم العلمي، النسبة المئوية لعدد المضادات الحيوية الموصوفة، النسبة المئوية لعدد الأدوية الموصوفة، وفي النسبة المئوية الموصوفة، واخترا النسبة المئوية للمهدئات الموصوفة وكانت بالتسلسل كالأتي: ٣، ٢ ، ١٢%، ٣٣.٣%، ١١٤٤ (و ٢٣.٨%، تدل هذه النتائج وبالمقارنة مع مقاييسها العالمية على الاستخدام غير الأمثل للدواء بالإضافة إلى طريقة الوصف السيء للواصفين بالرغم من إن مايقارب الـ ٢ من الواصفين هم من الأطباء الحاصلين على درجة عالية من التخصص. هذا يدعو وبصورة ملحة الى انقلاب حقيقي ومتابعة جدية لغرض الوصول إلى الاستخدام المثل للدواء بالإضافة إلى طريقة الوصف السيء للواصفين بالرغم من إن مايقارب الـ ٢٠% من الواصفين هم من الأطباء الحاصلين على درجة عالية من التخصص. هذا يدعو وبصورة ملحة الى القلاب حقيقي ومتابعة جدية الغرض الوصول إلى الاستخدام الأمثل للدواء والاستمر للواصفين من اجل الوصول إلى الوصول الى الوصفي الحربة الموسونة. ومتابعة جدية من الوصول إلى الاستخدام على درجة عالية من التخصص. هذا يدعو وبصورة ملحة الى انقلاب حقيقي ومتابعة جدية الغرض الوصول إلى الاستخدام الأمثل للدواء والتدريب المستمر للواصفين من اجل الوصول إلى الوصف الجيد للدواء.

Introduction

According to the World Bank⁽¹⁾, governments in developing countries expend between 20% and 50% of their national health budgets on drugs and medical sundries. Unfortunately, the World Health Organization (WHO) believes that much of such expenditure is misapplied, as irrational use of drugs is prevalent especially in developing countries⁽²⁾. Hence, governments, health workers and the community are concerned with the availability, handling, effectiveness and safe use of drugs. The prescribing of drugs is an important issue for the individual patient, since risks and benefits of the treatment directly affect the patient. Prescribed drugs are reimbursed by the society. Hence, prescribing of drugs is also a

key question from a public expense perspective. Financing of drugs is a vast problem, since costs for drugs are increasing and resources are limited⁽³⁾. Evaluation of costs and benefits for alternative treatment strategies is essential and rational drug use implies physicians' prescribing of drugs with favorable cost-benefit balances. Guidelines for recommended drugs are important for rational drug use. However, prescribing and adherence to prescribing guidelines vary between health care units ⁽⁴⁾, for example according to patient characteristics ⁽⁵⁻⁷⁾, physician characteristics ⁽⁶⁾, practice settings ⁽⁶⁾, budgetary policies ⁽⁸⁾ and country of residence (9).

Sources of drug information used by the physicians may be of additional significance ⁽¹⁰⁾. There are a limited number of objective measures or indicators that can describe the drug use situation in a country, region or individual health facility ⁽¹¹⁾. Those indicators include prescribing pattern, patient care and the facility indicators; the most reliable type is the prescribing indicators that measure the performance of health care providers in several key dimensions related to the appropriate use of drugs ⁽¹²⁾. This project was designed to evaluate prescribing pattern and rational drug use in Maysan governorate, Iraq.

Materials and Methods

This study was based on a surveillance conducted in private pharmacies in Maysan governorate during June to July 2005. The pharmacies were chosen randomly depending on systematic random sampling method ⁽¹³⁾. To calculate sampling interval, we divide the size of the list (no. of pharmacies in the governorate) by desired sample size (10 pharmacies), then choosing random number between 0 and 1 from the table of random numbers and multiplying it by sampling interval; this result must be rounded upward to get the number of the 1st pharmacy. A total of 585 prescriptions were selected randomly from the 10 pharmacies and the data obtained from each prescription were introduced in the prescribing indicator from (Table 1). In addition to those prescribing indicators, the degree of specialization of the physicians was taken into account to check whether it affects the prescribing pattern or not. Calculations were done using the following equations:

Average No. of drugs per each $Rx = \frac{Total no. of Drugs}{Total no. of Rxs}$
% of Drugs prescribed in Generic name = $\frac{Total no. of Drugs in generic names}{Total no. of Drugs prescribed} x100$
% of Rxs containing antibiotics (AB) = $\frac{No. of Rxs \ containing \ AB}{Total \ no. of \ Rxs} x100$
% of Rxs containing corticosteroids (CS.) = $\frac{No. of Rxs containing CS}{Total no. of Rxs} x100$
% of Rxs containing anxiolytics = $\frac{No. of Rxs containing Anxiolytics}{Total no. of Rxs} x100$
The ten pharmacies were coded as (A, B, C, D, E, F, G, H, I & J).

Sequence	No. of drugs/Rx	Drugs in Generic name	Antibiotics	Corticosteroids	Axiolytics
1.					
2.					
3.					
4.					
5.					
6.					
7.					
8.					
Total					
Average					
Percentage		%of total Drugs	% of AB in Rxs	% of CS in Rxs	% of anxiolytics in Rxs

Results

The prescribing indicators were calculated from each pharmacy and summarized in the table 2 in addition to the WHO standard value for each indicator ⁽¹⁴⁾. From table 2, we can find that the average number of drugs in prescription is 3.4, the

percentage of drugs prescribed in generic name is 12% which mean that the prescriber used the trade name in about 88% of the prescriptions. The percentage of AB prescription is 33.3% and the predominant type is cephalosporin derivatives (especially cephotaxim) which is 22% and then penicillin derivatives (especially amoxicillin) which is (17%), while the other types of AB represent the remaining percent. The percentage of the prescribed CS is 11.4%

and the Anxiolytics percentage was 23.8%. The comparisons between each prescribing indicators value with its counterpart WHO value were shown in figures 1-4.

Table 2:The values of each prescribing indicator for 10 pharmacies with the mean & the WHO standard value.

Indicator	P/A	P/B	P/C	P/D	P/E	P/F	P/G	P/H	P/I	P/J	Mean	WHO value
% Average no. of D/Rx	3.8	2.8	3.4	3.6	4.0	3.0	3.5	2.8	3.7	3.4	3.4	1.6-1.8
% of Drug in generic name	10	14	14	18	12	9	11	12	10	11	12%	100%
% of AB/Rx	30	30	34	35	38	40	28	26	39	32	33.3%	20-26.8%
% of CS./Rx	9	10.5	12	15.5	20	7	8	10.5	10.3	11.5	11.4%	1.6%
% of Anxiolytics/Rx	22	30	27	22	19	28	20	19	26	25	23.8	-

P: Pharmacy; D: Drug; Rx: Preemption; AB: Antiobiotic; CS: Corticosteroid

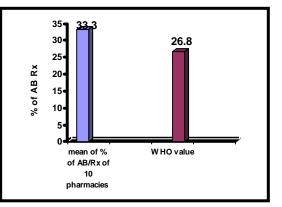

Figure 3: Comparison of the mean of percent AB/Rx of 10 pharmacies with WHO standard value.

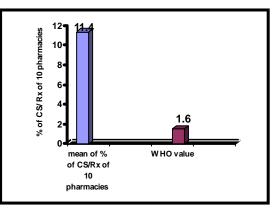

Figure 4: Comparison of the mean of percent CS/Rx of 10 pharmacies with WHO standard value.

Discussion

The core drug use indicators evaluate prescribers, patient care and the facility. Among the uses of these indicators are to describe current treatment practices, compare health facilities and prescribers and allow for identification of potential drug use problems that may affect patient care (15,16). The present study represent an insight on the prescribing pattern in private sector health facilities, because this sector is continuously growing and share important part in health providing services in Iraq; however, many serious problems and challenges emerged in this issue, including minimal, professional categorization with regard to drug prescribing, inefficient patient counseling, and finally high percentage of prescriptions are misused. The study showed that the average number of drugs in prescription that represent a polypharmacy approach (more then one drug in single prescription) was greater than that mentioned by WHO list; this will definitely lead to high consumption of drugs, loss of resources, increasing side effects due to drug interactions and misuse of drugs. Though no universal or even national standards exist for what the number of drugs in each prescription should be, the disparity between developing countries is worrisome and the number is quite high. Our findings are higher than those from Sudan 1.4 and Zimbabwe 1.3 (16). The prescription of several drugs per prescription (polypharmacy) is a serious problem; it has been attributed to patients' demand ⁽¹⁷⁾; desire to treat several ailments at the same time and inadequate diagnostic facilities to determine definitive cause of ill health ⁽¹⁸⁾. There is a need for education of patients and prescribers on the hazards of poly pharmacy. Also, managerial interventions to improve training of prescribers to ensure accurate diagnosis and provision of diagnostic facilities at the primary care level in Iraqi health facilities would alleviate such tendency. In the present study, the percentage of drugs prescribed in generic names is 12% only, which is very low percentage compared with the WHO standard value that may reach 100%; this could be due to low training prescribers, no health education about the importance of restriction in drug use. Moreover, many prescribers believe that the patient satisfy by receiving more than one or two drugs and finally lack of education facilities like leaflets or posters accessible by the prescribers ⁽¹⁹⁾. The percentage of AB prescribed in each prescription is 33.3%; this value is higher than WHO standard value (26.8%) which indicates the well known problem of misuse of AB with disputable

problems like hypersensitivity, higher cost, resistance and drug interaction. However, another study in Iraq reported more serious data in this respect that reflect antibiotics misuse in governmental institutions ⁽²⁰⁾. This could be due to the same reasons that Reez et al. (21) mentioned in his study, where physicians prescribe AB for any reason, just because they believe that the illness was attributed to bacterial infection. When comparing the percentage of the prescribed corticosteroids in our study (11.4) with the WHO value (1.6), the data revealed a real dangerous problem related to misuse of such agents with high and severe side effects. Choosing the anxiolytics as prescribing indicators in our study is due to the increase in consumption of such compounds in the community, especially during the period of unstable situation of the country and the well known consequences of war and its disasters. So, in spite of lack of the WHO value of prescribed anxiolytics, we reported a high percentage (23.8%); this is also a frightening percentage due to the wide range of side effects associated with these compounds. The last indicator considered in the present study is the level of specialization of the physician; the result showed a disappointed point, where 52% of the prescriptions categorized as bad prescribing pattern in this study, were ordered by highly specialized physicians; such finding reveal no relation between the highly specialization level and the prescribing pattern as one may expect. In conclusion, the rational use and prescription practice of drugs in Maysan/Iraq has many problems associated with misuse of drugs and the prevalent problems among physicians working in the private clinics; this require urgent intervention and follow up to promote the rational use of drug in this city.
